### 2.4

## Aiming for railway operations suitable for the 21st century

Enabling center and station operations, and supporting the transport operation control which provides safe and detailed services in the Tokyo metropolitan area.

### Concepts of ATOS

#### ● Transferring transport operation control from station to control center

On a railway line with high-density service, train operating services can be provided by the train control dispatch in real time, and automatic route control for all trains on all lines is performed. If there is a service interruption, regular service can be restored as soon as the cause is removed, and practical, highly reliable transport services are provided efficiently by controlling both stations and depots.

#### ● Improving services for passengers

Delayed passenger services can be provided to passengers by automatic announcements and passenger information displays. In case of accidents, providing information to the station staff makes it possible to guide passengers quickly and precisely.

#### ● The same train operation information available at stations and depots

In case of an interruption, train operating status information can be used efficiently for passenger information and safe maintenance work. Real-time operating status is available to stations, drivers and maintenance depots by information terminals connected with main computers via optical cables.

#### ● Improving efficiency and safety of maintenance work

Scheduling of maintenance work and route setting for maintenance vehicles are controlled automatically by transmitting commands to the work site by portable radio terminals.
